The availability of suitable basking sites is important for freshwater turtles. Basking in the sun elevates the turtle’s body temperature, permitting digestion of food. It also provides vitamin D and helps rid the body of ectoparasites (reference needed). Suitable basking sites must have exposure to sun, be accessible to turtles, and provide a safe site from predators and disturbance. Turtles are often seen basking on logs that are partially in water and partially on the shore. These slanted logs give turtles a choice to either climb completely out of the water or remain partially submerged. Other natural basking sites include rhizome mats of water lilies and exposed sites on the shoreline.

Water bodies with few natural basking sites may benefit from the addition of basking logs. Turtles readily use different types of installed logs and platforms, and the choice depends on availability of materials and resources.

**Installation of Basking Logs**

**Examples of basking log types**

1. Fallen logs from the vicinity of the water body (minimum diameter 30 cm; the larger the better); use machinery or roll the logs into water, then tow them with a boat to desired location.

2. Mill-end slabs with one side milled and the other side with bark attached (3 - 4 m long; 30 cm wide); these slabs are the by-product of lumber processing and can be obtained inexpensively or even for free - ask your local saw mills; the slabs are relatively light and can be carried into water by one person and then towed with a boat to desired location.

**Selecting location for basking logs**

- Select a sunny area, such as the north side of the water body.

- Select a secluded site away from people, pets, and areas where trails are close to the shore; turtles are wary of
disturbance from land.

- Use locations where the logs will be visible from a vantage point along the shore; this will help with monitoring of their use by turtles.

## Installing basking logs

- Place the logs perpendicular to the shoreline with one end firmly attached to the shore or shoreline vegetation; turtles are reluctant to use floating boards away from the shoreline.\(^1\)

- Attempt to place the log at an angle with the shore-end raised; this provides a range of distances from the water for turtles and allows for water level fluctuations.

- Anchor the log firmly in place at the shore-end; for mill-end slabs, drill a hole near the end and push a 5’ or longer rebar through the hole and into the shore, bottom substrate, or matted vegetation. For large logs, secure the end to trees or shrubs with rope, or use an anchor.
